Original article

Purification and partial amino acid sequence of propionicin PLG-1, a bacteriocin produced by *Propionibacterium thoenii* P127¹

HD Paik, BA Glatz*

Department of Food Science and Human Nutrition, Iowa State University, Ames, Iowa, USA

Summary — Propionicin PLG-1, a bacteriocin produced by *Propionibacterium thoenii* P127, was purified to homogeneity by ammonium sulfate precipitation followed by ion exchange column chromatography and reversed-phase high-performance liquid chromatography. According to amino acid composition analysis, propionicin PLG-1 has a calculated molecular weight of 9 328 and contains 99 amino acid residues, of which 42% are hydrophobic (Ala, Ile, Leu, Val and Pro). A 10-amino acid sequence from the N-terminal end was identified: NH₂-¹Asn-²Val-³Asp-⁴Ala(Thr)-⁵Arg-⁶Thr(Cys)-⁷Ala(Thr)-⁸Arg-⁹Thr(Ala)-¹⁰Pro. No homology of this sequence to sequences of other bacteriocins from lactic acid bacteria was seen in a search of the SWISS-PROT data bank.

bacteriocin / propionibacteria / propionicin / composition / purification

Résumé — Purification et séquence partielle des acides aminés de la propionicine PLG-1, une bactériocine produite par *Propionibacterium thoenii* P127. La propionicine PLG-1, une bactériocine produite par *Propionibacterium thoenii* P127, a été purifiée jusqu'à homogénéité par précipitation au sulfate d'ammonium suivie d'une chromatographie sur colonne d'échange d'ions et d'une chromatographie liquide haute-performance en phase inverse. D'après l'analyse de la composition en acides aminés, la propionicine PLG-1 a un poids moléculaire calculé de 9 328 et contient 99 résidus d'acides aminés, dont 42% sont hydrophobes (Ala, Ile, Leu, Val et Pro). Une séquence de 10 acides aminés de la partie N-terminale a été identifiée : NH₂-¹Asn-²Val-³Asp-⁴Ala(Thr)-⁵Arg-⁶Thr(Cys)-⁷Ala(Thr)-⁸Arg-⁹Thr(Ala)-¹⁰Pro. Aucune homologie de séquence avec d'autres bactériocines de bactéries lactiques n'a été trouvée en consultant la base de données SWISS-PROT.

INTRODUCTION

Bacteriocins are defined as bactericidal proteins with a narrow spectrum of activity targeted toward species related to the producer culture (Tagg *et al.*, 1976). Because bacteriocins are natural products of many microorganisms associated with foods, there is currently much interest in their use as natural food preservatives.

Numerous bacteriocins from gram-positive bacteria, particularly from lactic acid bacteria, have been identified (Klaenhammer, 1988), but only a few bacteriocins have been found in propionibacteria. Among the dairy propionibacteria, 2 bacteriocins have been reported: propionicin PLG-1 from *P. thoenii* P127 (Lyon and Glatz, 1991, 1993) and jensenin G from *P. jensenii* P126 (Grinstead and Barefoot, 1992). Propionicin PLG-1 is active against a variety of microorganisms (Lyon and Glatz, 1991) and has been shown to have a molecular weight of 10 000 after purification by ion exchange chromatography and isoelectric focusing (Lyon and Glatz, 1993).

Recently, many bacteriocins have been purified to homogeneity, and the amino acid sequences of many of these purified bacteriocins have been determined. Because bacteriocins are usually extracellular products, the first purification step concentrates the bacteriocin from the culture supernatants, usually by ammonium sulfate precipitation. Several chromatographic methods, such as gel filtration, ion exchange and/or hydrophobic interaction chromatography, have been recommended to achieve significant further purification. Reversed-phase chromatography was used as the final purification step for several bacteriocins, including pediocin PA-1 (Lozano *et al.*, 1992), curvacin A (Tichaczek *et al.*, 1992), sakacin A (Holck *et al.*, 1992), plantaricin A (Nissen-Meyer *et al.*, 1993), bavaricin A (Larsen *et al.*, 1993) and piscicollin 61 (Holck *et al.*, 1994).

Separation on reversed-phase supports in high-performance liquid chromatography (HPLC) has also been used to obtain highly purified preparations of leucocin A-UAL 187 (Hastings *et al.*, 1991), lactacin F (Muriana and Klaenhammer, 1991), mesentericin Y105 (Hechard *et al.*, 1992), lactacin 481 (Piard *et al.*, 1992), salivaricin A (Ross *et al.*, 1993), curvacin FS47 (Garver and Muriana, 1994) and staphylococcin 1580 (Sahl, 1994). The hydrophobic nature of these bacteriocins allows their purification by reversed-phase HPLC.

The goal of this study was the determination of amino acid composition and partial sequence of propionicin PLG-1. For such a study, highly purified bacteriocin was needed. This article reports an improved procedure for purification of propionicin PLG-1, as well as its amino acid composition and N-terminal amino acid sequence.

MATERIALS AND METHODS

Bacterial cultures and media

Producer strain *Propionibacterium thoenii* P127 was maintained as described previously by Lyon and Glatz (1991). Working cultures were propagated in sodium lactate broth (NLB) without shaking at 32°C. *Lactobacillus delbrueckii* ATCC 4797 was obtained from Dr S Barefoot (Clemson University, Clemson, SC). Stock cultures were maintained at -60°C in Lactobacilli MRS broth (Difco, Detroit, MI) containing 20% glycerol. Working cultures were prepared from stock cultures and grown in Lactobacilli MRS broth without shaking at 37°C.

Production of propionicin PLG-1

Strain P127 was grown in 14 l of NLB under controlled conditions in a 19 l fermenter (model NLF22, Bioengineering AG, Wald, Switzerland) in the Iowa State University Fermentation Facility. The fermentation was started with a 1% (v/v)

inoculum of an 18 h culture in NLB, and was incubated for 14 d at 32°C. Agitation was at 100 rpm without aeration. The pH was controlled at 7.0 ± 0.1 by the addition of 3 mol/l HCl or 3 mol/l NaOH.

Ammonium sulfate precipitation

The procedure reported by Lyon and Glatz (1993) was modified as follows: Ammonium sulfate was added slowly, with constant stirring, to culture supernatants (~150 ml) to 75% saturation at 4°C over approximately a 10 h period. Slow stirring was continued for an additional 3 h. Precipitated proteins were pelleted by centrifugation at $24\,000 \times g$ for 30 min at 4°C, resuspended in 20 mmol/l 2-N-morpholino-ethane-sulfonic acid (MES; Sigma Chemical Co, St Louis, MO) buffer, pH 6.5, + 0.1% Tween 80, and dialyzed against 3 l of 10 mmol/l MES buffer, pH 6.5, + 0.1% Tween 80, for 12–18 h in Spectra-Por no 3 dialysis tubing (molecular mass cutoff, 3500; Spectrum Medical Industries, Los Angeles, CA).

Dialysis against polyethylene glycol

When reduction of sample volume was required, the sample in dialysis tubing was placed in a weighboat containing about 50 g of polyethylene glycol (PEG; Mr 15 000–20 000; Sigma Chemical Co, St Louis, MO) and incubated for 1–3 h at 4°C.

Ion exchange chromatography

The procedure reported by Lyon and Glatz (1993) was modified as follows: The column dimensions were 1.6 x 23 cm and the bed volume of the carboxymethyl Sepharose (Sigma) was 39 ml. The column was equilibrated with 20 mmol/l MES buffer (pH 6.5) + 0.1% Tween 80 and concentrated partially purified bacteriocin was applied in a descending mode at 4°C. The column was washed with several volumes of the same loading buffer to separate unadsorbed proteins and then adsorbed proteins were eluted from the column by means of a linear salt gradient (0 to 1.0 mol/l NaCl, 500 ml) in MES buffer (pH 6.5) + 0.1% Tween 80. Fractions (4.2 ml) were monitored for

protein content by absorbance at 280 nm and assayed for bacteriocin activity.

Reversed-phase high-performance liquid chromatography

Samples (20 µl) were applied to a 30 cm µBondapak C₁₈ column (Supelcosil LC-18; Supelco, Inc, Bellefonte, PA), which was equilibrated with 0.1% (v/v) trifluoroacetic acid (TFA; Sigma), in a Shimadzu HPLC (model LC-600, Shimadzu Corporation, Kyoto, Japan). Elution was with a 90 min linear gradient from 100% buffer A to 100% buffer B, then 20 min at 100% buffer B. Buffer A was 0.1% (v/v) TFA in water; buffer B was 0.1% TFA in 100% 2-propanol (Fisher Scientific, Fair Lawn, NJ). The flow rate was maintained at 0.4 ml/min and the eluate was monitored at 220 nm by means of a Shimadzu UV-Vis Spectrophotometer (model SPD-6AV, Shimadzu Corporation). Fractions of 2 ml volume were collected and assayed for bacteriocin activity.

SDS-PAGE

Aliquots (3–5 µl) of fractions obtained from HPLC were subjected to SDS-PAGE. Approximately 50–75 ng protein were loaded into each lane. Electrophoresis was performed using 10–20% gradient polyacrylamide gels (Mini-PROTEAN II Ready Gels; Bio-Rad Laboratories, Hercules, CA), with the buffer system described by Laemmli (1970) at constant voltage (100 V) for 100 min. Gels were fixed in 30% ethanol–10% glacial acetic acid solution for 1 h and silver stained according to the manufacturer's instructions (Bio-Rad).

Protein determination

Protein content of samples at the different purification steps was determined by the bicinchoninic acid (BCA) assay (Stoscheck, 1990) according to the manufacturer's specifications (Pierce Chemical Co, Rockford, IL). Bovine serum albumin (BSA; Sigma) was used as the protein standard. Enhanced protocol, which involved color development at 60°C for 30 min, was used.

Amino acid composition and sequence analysis

Amino acid composition and sequence analysis of purified propionin PLG-1 were performed in the Iowa State University Protein Facility. Amino acid analysis was performed with an amino acid analyzer model 420A (Perkin-Elmer, Applied Biosystems Div, Foster City, CA) equipped with an integrated hydrolysis system. The amino acid sequence was determined by Edman degradation (Edman and Begg, 1967) using an Applied Biosystems 477A protein sequencer (Perkin-Elmer, Applied Biosystems Div) with an on-line 120A phenylthiohydantoin amino acid analyzer.

The sequence was compared to those in the SWISS-PROT data base, by using the Sequence Analysis Software Package, licensed from the Genetics Computer Group (University of Wisconsin, Madison, WI) (Devereux *et al.*, 1984).

Bacteriocin assay

The well diffusion assay as described by Lyon and Glatz (1993) was modified as follows: The basal layer of NLA contained 2.5% agar and 0.1% Tween 80 and was 5 mm deep. After pouring the agar layer, plates were incubated 24 h at room temperature before wells were cut. After 7 mm diameter wells were cut, plates were incubated at 37°C for 2 h or at room temperature for 2 d to dry the plates and to facilitate sample diffusion into the agar. Indicator strain was *L. delbrueckii* ATCC 4797, which was added to 5 ml soft agar (0.7% agar) overlays of MRS medium at about 10^7 cells per overlay. Serially diluted samples (200 μ l) were added to wells, allowed to diffuse at 4°C, and the base agar was flipped into the Petri dish lid before the overlay was applied. Plates were incubated anaerobically in the BBL Gas-Pak system (Becton Dickinson, Cockeysville, MD) for 12 h at 37°C before diameters of zones of inhibition were measured. Minimum detectable zone diameter was 9 mm (1 mm beyond well diameter). Activity units (AU) per ml of original culture were calculated from the reciprocal of the highest dilution that produced a detectable zone of inhibition. If the inhibition zone at this dilution was large (>11 mm diameter), additional incremental dilutions were assayed to define the titer more precisely.

RESULTS

Purification of bacteriocin

Propionin PLG-1 was previously purified to homogeneity by ammonium sulfate precipitation, ion exchange chromatography and isoelectric focusing (Lyon and Glatz, 1993). To obtain highly purified preparations for amino acid composition and sequence analysis, the previously reported purification scheme was followed but was modified as required. Some changes in ammonium sulfate precipitation conditions and ion exchange chromatography were made. Reversed-phase HPLC replaced isoelectric focusing as the final step.

The purification steps and their associated recoveries of propionin PLG-1 are given in table I. Propionin PLG-1 was purified from the supernatant fraction of cultures grown in semidefined medium, sodium lactate broth, to minimize the presence of contaminating proteins. In preliminary studies, some bacteriocin activity was detected in the proteins precipitated at 50% saturation of ammonium sulfate. Therefore, to avoid loss of bacteriocin, a single precipitation at 75% saturation of ammonium sulfate was used.

Upon consideration of the amount of protein to be applied to the ion exchange Carboxymethyl Sepharose column and the bed volume that could accommodate this amount, a smaller column (1.6 x 23 cm, 39 ml bed volume) was used than in previous work (Lyon and Glatz, 1993). After application of the bacteriocin preparation, the column was washed with MES buffer. A large protein peak was eluted within the first 63 ml (15 fractions) of buffer (fig 1). This peak of unadsorbed proteins was completely separated from a protein peak eluted at about 0.04 to 0.16 mol/l NaCl. A small portion at the tail of this peak contained 60% of the bacteriocin activity originally applied to the column.

The previously reported final step in propionin purification was by isoelectric focusing (Lyon and Glatz, 1993). However, despite several attempts with different combinations of ampholytes, we were not able to obtain a single protein band after isoelectric focusing. Therefore, reversed-phase HPLC was tried as an alternative method. Reversed-phase HPLC can be used for purification and/or large-scale preparation of proteins that are stable in organic mobile phases, or proteins that can renature after unfolding occurs during the elution process (Chicz and Regnier, 1990). A number of bacteriocins have been purified by this method.

Various acids and organic solvents used in reversed-phase HPLC were first tested for their effect on propionin activity. Equal volumes of partially purified bacteriocin and methanol, 2-propanol, acetonitrile, ethanol, 0.2% (v/v) trifluoroacetic acid (TFA) and 2% (v/v) phosphoric acid were incubated for 2 h, then assayed for bacteriocin activity in the well diffusion assay. No effect of any of these solvents and acids on measured activity was seen, nor did the solvents and acids inhibit the indicator strain. The TFA and 2-propanol were selected for use because of

their excellent solubilizing properties (Chicz and Regnier, 1990).

The 5 fractions from the ion exchange column containing bacteriocin activity (21 ml total volume) were pooled, reduced to 0.4 ml volume by dialysis against PEG to concentrate the bacteriocin, and 20 μ l of this concentrate were applied to an analytical C_{18} reversed-phase HPLC column. A preparative scale column would be preferred when large quantities of purified protein are desired, but the column used in this study was sufficient to produce enough protein for subsequent composition and sequence analyses. The elution of the propionin preparation from the C_{18} column was monitored at A_{220} . Two independent trials were performed, and gave similar results. One trial is shown in figure 2. Several small, sharp peaks were seen, but bacteriocin activity was detected only in 10 fractions, with highest activity seen in 4 fractions containing a single peak that eluted with 84% 2-propanol. A total of 56 fractions were obtained from the column. When the purity of the fractions containing bacteriocin activity was assessed by SDS-PAGE, a single protein band with apparent molecular weight 9 690 was detected in 4 fractions with high

bacteriocin activity (fig 3). The other fractions contained this band plus possibly an additional faint band. We concluded that the 9 690 Mr protein purified at this step is propionicin PLG-1.

⁶Thr(Cys)-⁷Ala(Thr)-⁸Arg-⁹Thr(Ala)-¹⁰Pro. When an amino acid is listed in parentheses after another, this indicates that either may be present, with the first being more likely. This amino acid sequence was compared

Amino acid composition and sequence

The amino acid composition of purified propionicin PLG-1 is given in table II. Propionicin PLG-1 contains 99 amino acid residues with a calculated molecular weight of 9 328. This agrees closely with the molecular weight of 9 690, determined by the position of propionicin PLG-1 compared to molecular weight markers in 10–20% gradient gels in SDS-PAGE (fig 3). Neutral (Gly) and hydrophobic (Ala, Ile, Leu, Val and Pro) residues make up a significant portion of propionicin PLG-1: 20 and 42%, respectively. It should be noted that tryptophan can be destroyed by the acid hydrolysis method employed. If propionicin PLG-1 contained some tryptophan residues, they could go undetected.

The sequence of the first 10 N-terminal amino acids was determined as follows: NH₂-¹Asn-²Val-³Asp-⁴Ala(Thr)-⁵Arg-

to others listed in the SWISS-PROT data bank. No homology to other listed proteins, including other bacteriocins from lactic acid bacteria, was found. Therefore, propionin PLG-1 seems to be different from other previously reported bacteriocins from lactic acid bacteria.

Purified propionin PLG-1 obtained from reversed-phase HPLC was stable to storage in the lyophilized state at both 4 and -60°C for 3 months. No significant change

in activity was seen in samples stored over this period (data not shown).

DISCUSSION

A highly purified bacteriocin was obtained in this study through a sequence of steps including ammonium sulfate precipitation, ion exchange chromatography and reversed-phase HPLC. Bacteriocin was precipitated from more than 1 l of culture supernatant. The addition of so much ammonium sulfate to such large volumes of culture supernatant took over 10 h; the samples were further stirred slowly at 4°C for an additional 3 h. This much longer incubation with ammonium sulfate compared to that used previously with smaller (50–100 ml) supernatants (usually 3 h to add salt plus an additional 30 min of stirring after salt addition) seemed to improve bacteriocin recovery. For example, in 1 batch, the measured activity in a 50 ml sample was 2.4-fold lower than that measured in a 1 l sample. Possibly the longer incubation facilitates interaction of bacteriocin molecules with each other or with other proteins that can then precipitate. Other bacteriocins have been reported to precipitate poorly. For example, lactacin F (Muriana and Klaenhammer, 1991) and lactocin S (Mortvedt *et al*, 1991) have been reported to be lost as a floating fraction during ammonium sulfate precipitation, possibly due to their hydrophobic character. Slow addition of ammonium sulfate plus continued stirring for at least 3 h are recommended for bacteriocin recovery.

A single-step ammonium sulfate precipitation at 75% saturation was used, rather than taking the proteins precipitated between 50 and 75% saturation, because we observed that some bacteriocin activity was lost in the proteins precipitated at 50% saturation. However, this change affected the amount of protein present in the precipitate and the fold purification of bacteriocin

obtained. In the current study, an estimated 321-fold purification was obtained after ammonium sulfate precipitation. This compares to a 600-fold purification in this step reported previously (Lyon and Glatz, 1993).

For ion exchange chromatography, a small column with a correspondingly small bed volume was used. Bacteriocin was eluted from the column in a tight band, and was completely separated from unadsorbed proteins. However, the elution profile from the ion exchange column indicated that propionacin was not completely separated from other adsorbed proteins. Therefore, a final step was necessary for complete purification. Reversed-phase HPLC proved to be an effective final step.

Recently, reversed-phase HPLC has been used to obtain highly purified preparations of a number of other bacteriocins, including leucocin A-UAL 187 (Hastings *et al.*, 1991), lactacin F (Muriana and Klaenhammer, 1991), mesentericin Y105 (Hechard *et al.*, 1992), lactacin 481 (Piard *et al.*, 1992), salivaricin A (Ross *et al.*, 1993), curvaticin FS47 (Garver and Muriana, 1994) and staphylococcin 1580 (Sahl, 1994). The hydrophobic nature of these bacteriocins, and the apparent hydrophobicity of propionacin PLG-1, allows their purification by reversed-phase HPLC. Hydrophobicity may also contribute to the tendency of many bacteriocins from lactic acid bacteria to associate with other substances to form large macromolecular complexes. For instance, lactacin B (Barefoot and Klaenhammer, 1984), helveticin J (Joerger and Klaenhammer, 1986) and lactacin F (Muriana and Klaenhammer, 1991) have been shown to form associations with lipid and carbohydrate. Bacteriocins from *Lactobacillus* sp have been reported to associate with protein-detergent (Tween 80 in MRS broth) micelles (Garver and Muriana, 1994). Association of propionacin PLG-1 with other proteins or aggregation of several molecules of propionacin into multimeric forms is the

probable reason it is seen to elute in gel filtration at apparent molecular weights of more than 150 000 and approximately 10 000, while under dissociating conditions it elutes at 10 000 (Lyon and Glatz, 1993). As has been demonstrated most completely for the bacteriocins nisin and subtilin (Montville and Kaiser, 1993), the hydrophobicity of these molecules promotes interaction with cell membranes, leading to bactericidal action through the formation of pores in the membranes.

The successful determination of the amino acid composition and the N-terminal sequence of propionacin PLG-1 indicates that propionacin does not contain unusual or modified amino acids, as is the case with lantibiotics such as nisin, nor does it have a blocked N-terminus. It does contain a relatively high percentage of hydrophobic amino acids; such hydrophobicity is common among bacteriocins of lactic acid bacteria (Garver and Muriana, 1994). For example, about 50% of the amino acids are hydrophobic in lactococcin A (Holo *et al.*, 1991), lactocin S (Mortvedt *et al.*, 1991) and curvaticin FS47 (Garver and Muriana, 1994). However, curvacin P and sakacin P (Tichaczek *et al.*, 1992) contain only about 20–25% hydrophobic residues. The high proportion of glycine residues in propionacin should provide a significant amount of flexibility to the molecule (Garver and Muriana, 1994). Glycine occupies very little space and allows a wide range of conformations in the folding of polypeptide chains (Stryer, 1988).

Propionacin PLG-1 was not found to share homology with other proteins (including other bacteriocins) listed in the SWISS-PROT data bank. In contrast to this result, many bacteriocins of lactic acid bacteria have been reported to share significant degrees of homology. For example, bavaricin A (Larsen *et al.*, 1993) was found to share 66% homology with pediocin PA-1 produced by *Pediococcus acidilactici* (Marugg *et al.*, 1992) and 39% homology with leucocin A-UAL

(Hastings *et al*, 1991). Sakacin A (Holck *et al*, 1992) was reported to share some homology, especially in the N-terminal region, with the newly sequenced bacteriocins leucocin A-UAL187 (Hastings *et al*, 1991), pediocin PA-1 (Lozano *et al*, 1992) and sakacin P (Tichaczek *et al*, 1992). The amino acid sequence of leucocin B-Ta11a (Felix *et al*, 1994) was reported to be significantly homologous to the sequence of leucocin A-UAL187 (Hastings *et al*, 1991). A bacteriocin produced by *Pediococcus acidilactici* was shown to have the identical primary amino acid sequence as pediocin PA-1 (Henderson *et al*, 1992) and was, in fact, the same molecule. Staphylococcin 1580 (Sahl, 1994) was shown to be identical to epidermin, a lantibiotic, by amino acid composition analysis, determination of molecular weight and limited N-terminal sequencing.

In conclusion, we have obtained a highly purified preparation of propionin PLG-1 by sequential steps of ammonium sulfate precipitation, ion exchange chromatography and reversed-phase HPLC. The amino acid sequence of propionin PLG-1 indicates that it is different from other previously reported bacteriocins from lactic acid bacteria. Its hydrophobic nature lends support to the suggestion that propionin PLG-1, like other bacteriocins, interacts with and may have as its primary target the cytoplasmic membrane of sensitive organisms.

ACKNOWLEDGMENTS

We are indebted to Dr E Hammond who provided use of his HPLC, Dr A Myers who provided access to the SWISS-PROT data base through the Sequence Analysis Software Package, the Iowa State University Protein Facility for amino acid composition and sequence analysis and the Iowa State University Fermentation Facility for use of fermentation equipment. This work was supported by the Binational Agricultural Research and Development Fund (BARD), grant no US-2080-91.
